What is chance

How to measure chance

Birthday problem

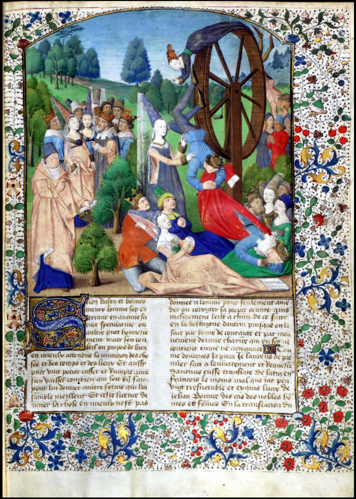
Rolling three dices

Poker

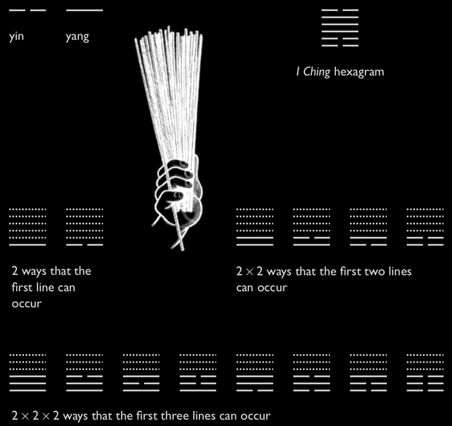
What is CHANCE?

Tyche – The Greek goddess of chance

Fortuna – The goddess of chance in Roman religion



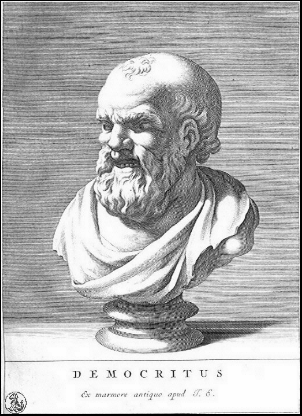
I Ching in China (~ 6th century B.C.)



[1]

[1] Image is from Bennett (1998), *Randomness*, Harvard University Press.

Democritus (460 – 370 BC)
— Father of modern science



Atomic theory of the universe:

A physical chance affecting all the atoms
that made up the universe.

Games of chance
— using knucklebones or dice

Known to Egyptians, Babylonians, Romans, ...

There was no qualitative theory of chance in these times.

How to measure chance?

How about measure length?

The determination of a "right and lawful rood" or rod in the early sixteenth century in Germany by measuring an essentially random selection of 16 men as they leave church [2].

[2] Stephen Stigler (1996). Statistics and the Question of Standards, *Journal of Research of the National Institute of Standards and Technology*, vol. 101.

The same for chance

To measure probability,

1. we first find or make equally probable cases,
2. then we count.

The probability of an event A, denoted by $\mathbb{P}(A)$, is then

$$\mathbb{P}(A) = \frac{\text{no. of cases in which } A \text{ occurs}}{\text{total no. of cases}}.$$

The same for chance

To measure probability,

1. we first find or make equally probable cases,
2. then we count.

The probability of an event A, denoted by $\mathbb{P}(A)$, is then

$$\mathbb{P}(A) = \frac{\text{no. of cases in which } A \text{ occurs}}{\text{total no. of cases}}.$$

The same for chance

To measure probability,

1. we first find or make equally probable cases,
2. then we count.

The probability of an event A, denoted by $\mathbb{P}(A)$, is then

$$\mathbb{P}(A) = \frac{\text{no. of cases in which } A \text{ occurs}}{\text{total no. of cases}}.$$

The same for chance

To measure probability,

1. we first find or make equally probable cases,
2. then we count.

The probability of an event A, denoted by $\mathbb{P}(A)$, is then

$$\mathbb{P}(A) = \frac{\text{no. of cases in which } A \text{ occurs}}{\text{total no. of cases}}.$$

The same for chance

To measure probability,

1. we first find or make equally probable cases,
2. then we count.

The probability of an event A, denoted by $\mathbb{P}(A)$, is then

$$\mathbb{P}(A) = \frac{\text{no. of cases in which } A \text{ occurs}}{\text{total no. of cases}}.$$

Now we see that probability has to satisfy the following properties:

1. Probability should be never negative.
2. If A occurs in all cases, then $\mathbb{P}(A) = 1$.
3. If A and B never occur in the same case, then

$$\mathbb{P}(A \text{ or } B) = \mathbb{P}(A) + \mathbb{P}(B).$$

In particular, the probability of an event not occurring is equal to

$$\mathbb{P}(\text{not } A) = 1 - \mathbb{P}(A).$$

Now we see that probability has to satisfy the following properties:

1. Probability should be never negative.
2. If A occurs in all cases, then $\mathbb{P}(A) = 1$.
3. If A and B never occur in the same case, then

$$\mathbb{P}\,(A \text{ or } B) = \mathbb{P}(A) + \mathbb{P}(B).$$

In particular, the probability of an event not occurring is equal to

$$\mathbb{P}(\text{not } A) = 1 - \mathbb{P}(A).$$

Now we see that probability has to satisfy the following properties:

1. Probability should be never negative.
2. If A occurs in all cases, then $\mathbb{P}(A) = 1$.
3. If A and B never occur in the same case, then

$$\mathbb{P}(A \text{ or } B) = \mathbb{P}(A) + \mathbb{P}(B).$$

In particular, the probability of an event not occurring is equal to

$$\mathbb{P}(\text{not } A) = 1 - \mathbb{P}(A).$$

Now we see that probability has to satisfy the following properties:

1. Probability should be never negative.
2. If A occurs in all cases, then $\mathbb{P}(A) = 1$.
3. If A and B never occur in the same case, then

$$\mathbb{P}\left(A \text{ or } B\right) = \mathbb{P}(A) + \mathbb{P}(B).$$

In particular, the probability of an event not occurring is equal to

$$\mathbb{P}(\text{not } A) = 1 - \mathbb{P}(A).$$

Now we see that probability has to satisfy the following properties:

1. Probability should be never negative.
2. If A occurs in all cases, then $\mathbb{P}(A) = 1$.
3. If A and B never occur in the same case, then

$$\mathbb{P}\left(A \text{ or } B\right) = \mathbb{P}(A) + \mathbb{P}(B).$$

In particular, the probability of an event not occurring is equal to

$$\mathbb{P}(\text{not } A) = 1 - \mathbb{P}(A).$$

How to generate the equi-probable cases?

Prim sticks (variations of dice) [3] and deck of poker...

[3] Image is from Bennett (1998), *Randomness*, Harvard University Press.

Girolamo Cardano (1501 – 1576), an Italian polymath, whose interests and proficiencies ranged through those of mathematician, physician, biologist, physicist, chemist, astrologer, astronomer, philosopher, writer, and gambler. He was one of the most influential mathematicians of the Renaissance, and was one of the key figures in the foundation of probability and the earliest introducer of the binomial coefficients and the binomial theorem in the Western world.

Birthday Problem

Question: How likely do two students have the same birth day if there are

- 2
- 5
- 15
- 23
- 46
- 64
- 366

students in the class?

Assuming that

1. each year has 365 days (i.e., neglecting leap years),
2. birthdays are equi-probable,
3. birthdays are independent (no twins in the class).

Question: How likely do two students have the same birth day if there are

- 2
- 5
- 15
- 23
- 46
- 64
- 366

students in the class?

Assuming that

1. each year has 365 days (i.e., neglecting leap years),
2. birthdays are equi-probable,
3. birthdays are independent (no twins in the class).

- Suppose $n = 5$.
- Let A be the **event** that two students have the same birth day.
- Let (A) denote the probability that this event A will happen.
- It is not easy to compute (A) directly.
- However, one can compute (A'), – the complement of event A, namely,

  the probability that no two students have the same birthday, or

  all students have different birthday,

  as follows:

$$\mathbb{P}(A') = \frac{365}{365}\frac{364}{365}\frac{363}{365}\frac{362}{365}\frac{361}{365}$$

- Hence,

$$\mathbb{P}(A) = 1 - (A') = 1 - \frac{365}{365}\frac{364}{365}\frac{363}{365}\frac{362}{365}\frac{361}{365} \approx 0.027.$$

- Suppose $n = 5$.
- Let A be the **event** that two students have the same birth day.
- Let (A) denote the probability that this event A will happen.
- It is not easy to compute (A) directly.
- However, one can compute (A'), – the complement of event A, namely,

  the probability that no two students have the same birthday, or

  all students have different birthday,

  as follows:

$$\mathbb{P}(A') = \frac{365}{365}\frac{364}{365}\frac{363}{365}\frac{362}{365}\frac{361}{365}$$

- Hence,

$$\mathbb{P}(A) = 1 - (A') = 1 - \frac{365}{365}\frac{364}{365}\frac{363}{365}\frac{362}{365}\frac{361}{365} \approx 0.027.$$

- Suppose $n = 5$.
- Let A be the **event** that two students have the same birth day.
- Let (A) denote the probability that this event A will happen.
- It is not easy to compute (A) directly.
- However, one can compute (A'), – the complement of event A, namely,

  the probability that no two students have the same birthday, or

  all students have different birthday,

  as follows:

$$\mathbb{P}(A') = \frac{365}{365}\frac{364}{365}\frac{363}{365}\frac{362}{365}\frac{361}{365}$$

- Hence,

$$\mathbb{P}(A) = 1 - (A') = 1 - \frac{365}{365}\frac{364}{365}\frac{363}{365}\frac{362}{365}\frac{361}{365} \approx 0.027.$$

A question asked by *Grand Duke of Tuscany* to *Galileo* in early seventh century

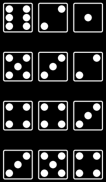
Three dice are thrown, such as

9 :

10 :

11 :

12 :



Counting combinations of numbers, 10 and 11 can be made in 6 ways, as can 9 and 12. Yet it is known that long observation has made dice-players consider 10 and 11 to be more advantageous than 9 and 12. How can this be?
